Introduction Replication and Comparison

REPLICATION OF "EDUCATIONAL EXPANSION AND ITS HETEROGENEOUS RETURNS FOR WAGE WORKERS" BY MICHAEL GEBEL AND FRIEDHELM PFEIFFER

Luisa Hammer and Marcelo Avila

22 Nov 2018

Introduction

L: OUTLINE

- Theoretical Framework
 - Gebel & Pfeiffer (2010)
 - Returns to education
- Empirical framework
 - Correlated random coefficients model
 - Conditional Mean approach
 - Control funtion approach
- Replication
 - Set-up
 - Code
 - Comparison of results

THEORETICAL FRAMEWORK

L: Summary of Gebel and Pfeiffer (2010)

- Basic idea: examine evolution of returns to education in West German labour market.
- Focus on change in returns to education over time as a consequence to education expansion in Germany.
- methodology:
 - Wooldrigdge's (2004) conditional mean independence
 - Garen's (1984) control function approach, that requires an exclusion restriction
 - as well as OLS regression
- data: SOEP 1984-2006

L: Background Information I

Increase in educational attainment

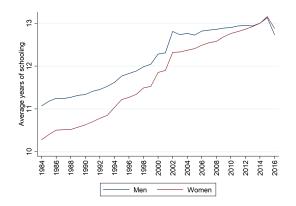

FIGURE 1: Source: SOEP 1984-2016, own estimations.

L: Background Information II

How can educational expansion affect the returns to education?

- Standard theory: an increase of labor supply of high-skilled workers should decrease the returns to education
- High-educated workers with higher unobserved motivation / ability which positively affects wages
- If more less talented are accepted to higher education, this should decrease the average productivity levels of higher educated workers
 -> overall effect not clear

Problems in the estimation of returns to education

- unobserved characteristics leading to **selection bias**:
 - higher ability and motivation to stay longer in education.
 - select jobs with higher expected returns.

ECONOMETRIC APPROACH

M: Empirical Framework (Derivation) I

The study is based on the **correlated random coefficient model** (Wooldridge, 2004 and Heckman and Vytlacil, 1998) specified as:

$$\ln Y_i = a_i + b_i S_i$$

with
$$a_i = a'X_i + \varepsilon_{ai}$$
, and $b_i = b'X_i + \varepsilon_{bi}$

where $\ln Y_i$: log of wages and S_i years of schooling of individual i

- The model has, therefore, an individual-specific intercept a_i and slope b_i dependent on observables X_i and unobservables ε_{ai} and ε_{hi} .
- Do not assume that b_i and S_i are independent -> Individuals with "unobservably" higher expected benefits from education are more likely to remain longer in education -> b_i may be correlated with S_i indicating positive self-selection.

M: Empirical Framework (Derivation) II

 focus: estimate average partial effect (APE), which is the return per additional year of education for a randomly chosen individual (or averaged across the population)

$$E(\partial \ln Y/\partial S) = E(b_i) = \beta$$

In case of homogeneous returns to education the wage equation reduces to:

$$\ln Y_i = a'X_i + \bar{b}S_i + \varepsilon_{ai}$$

- Unobserved heterogeneity may only affect the intercept of the wage equation.
- \blacksquare still potential endogeneity if ε_{ai} correlates with S_i

M: Empirical Framework (Intuition) I

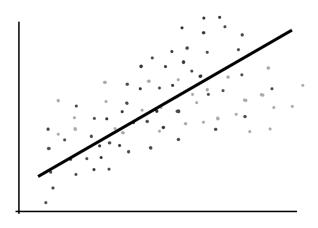

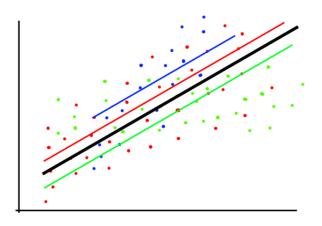

FIGURE 2: Simple OLS

M: Empirical Framework (Intuition) II

 $\ensuremath{\mathrm{Figure}}$ 3: Multiple OLS with homogeneous return to Educ

M: Empirical Framework (Intuition) III

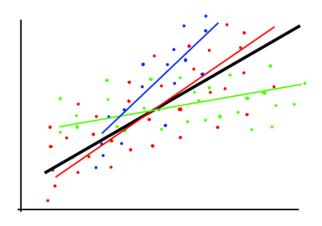

FIGURE 4: Correlated Random Coefficient Model

M: Distinction to conventional methods

- OLS
 - ability and "background" bias
- IV Methods:
 - suitable if assume homogeneous returns to education.
 - if education is correlated with unobserved individual heterogeneity, IV methods may fail to identity APE.
 - alternative: Local Average Treatment Effect if interested in effect of educational policy reforms.

M: Conditional Mean Independence

According to Wooldridge (2004, pg.7), APE is identified if:

$$E(\ln Y_i \mid a_i, b_i, S_i, X_i,) = E(\ln Y_i \mid a_i, b_i, S_i) = a_i + b_i S_i \qquad (A.1)$$

$$E(S_i \mid a_i, b_i, X_i) = E(S_i \mid X_i) \text{ and } \operatorname{Var}(S_i \mid a_i, b_i, X_i) = \operatorname{Var}(S_i \mid X_i) \tag{A}$$

- (A.1): Redundancy of X_i given a_i and b_i and S_i .
- (A.2): In the first two conditional moments of S_i , a_i and b_i are redundant -> "Staying longer in Education is determined by X covariates".
- Basically: X_i should be "good predictors" of treatment S_i (Wooldridge 2004, pg.7).

M: Estimator for β and GLM

The **APE** can be estimated by:

$$\hat{\beta} = \frac{1}{N} \sum_{i=1}^{N} \left(\left(S_i - \hat{E}(S_i \mid X_i) \ln Y_i \right) \middle/ \hat{Var}(S_i \mid X_i) \right)$$

$$E(S_i \mid X_i) = e^{\gamma X_i} \quad \text{and} \quad Var(S_i \mid X_i) = \sigma^2 e^{\gamma X_i}$$

Where σ^2 can be consistently estimated by the mean of squared Pearson residuals and standard errors are bootstrapped.

L: CONTROL FUNCTION APPROACH I

- Based on proposition by Garen (1984).
- CF approach can identify APE in heterogeneous returns while standard IV approach may not.
- Similar to Heckman two-step estimator.
- Models schooling choice explicitly in first step

First step: modelling schooling choice

$$S_i = c'X_i + dZ_i + v_i \quad \text{with} \quad E(v_i \mid Z_i, X_i) = 0$$

where:

- lacksquare X_i and Z_i influence the educational decision.
- $\ \ \, v_i \colon$ Error term incorporating unobserved determinants of education choice.

L: CONTROL FUNCTION APPROACH II

- \blacksquare Z_i : Exclusion restriction (instrument).
- $lackbox{v}_i$, $arepsilon_{ai}$ and $arepsilon_{bi}$ are normally distributed with zero means and positive variances, that are possibly correlated
- $lackbox{ }v_i$ is positive if an individual acquires higher education than expected conditional on observed characteristics

Second step: augmented wage equation

$$\ln Y_i = a_i + \beta S_i + \gamma_1 v_i + \gamma_2 V_i S_i + w_i$$

where:

- lacksquare γ_1 and γ_2 are the control functions
 - $\label{eq:gamma_1} \blacksquare \ \gamma_1 = cov(\varepsilon_{ai}, v_i) / var(v_i)$
 - $\label{eq:gamma_2} \blacksquare \ \gamma_2 = cov(\varepsilon_{bi}, v_i) / var(v_i)$
- \blacksquare $E(w_i \mid X_i, S_i, v_i) = 0$ (as shown in Heckman / Robb, 1985)

L: Control Function Approach III

Interpretation of the coefficients of the control functions

- γ_1 measures the effect of those unobserved factors that led to overor under-achievement in education on the wage
 - Thus, if γ_1 is positive, the unobserved factors affect schooling and wages positively
- $\ \ \, \gamma_2$ describes how this effect changes with increasing levels of education
 - Positive coefficient would indicate that those with unexpected educational "over-achievement" tend to earn higher wages

EPLICATION AND COMPARISON
ESULTS
ONCLUSION

REPLICATION AND COMPARISON

L: Set-up

- We use the same sample: West Germans (not foreign-born or self-employed) between 25 and 60 years who work full-time
- We have less observations than Gebel and Pfeiffer (2010) per survey year after we delete all observations with missing values
- Yet, we extend the observation period until 2016
- Three estimation methods: OLS, CMI CF
- control variables: age and age squared, gender, father's education, mother's education, father's occupation, rural or urban household, number of siblings (as instrument)

REPLICATION AND COMPARISON

```
*** GLM regression with Poisson distribution
glm school sex age age_sq rural edu_f occ_f edu_m, family(poisson) link(log)

*** Predict conditional mean and extract pearson residuals
predict condMean, mu
predict res_pears, pearson

*** Calculate residual
gen resid = school - condMean

*** Estimate sigma^2
egen sigma_sq_pears = mean(res_pears^2)

*** generate APE
egen bCMI = mean((resid*lnw)/ (sigma_sq_pears*condMean))
```

M: STATA IMPLEMENTATION (BOOTSTRAPPING)

```
program define myCMI, rclass // return scalar as r() macro
 preserve // using preserve/restore due to repeated sampling
   bsample // setup for boostrap sampling
    * run GLM estimation as in previous slide *
    *** Return variable of interest
    local bCMT=bCMT
    return scalar bCMI return = `bCMI'
 restore
end
```

L: STATA IMPLEMENTATION (CF)

```
* First step: Estimate the reduced form of schooling, i.e. regress
* schooling on all exogeneous variables including the instrument (siblings)
reg school sex age age_sq rural edu_f edu_m occ_f sibl if syear==`n'

* Obtain the residuals
predict v`n', res

* Second step: Estimate the structural equation and include the
* residuals from the reduced form as an additional regressor
reg lnw school sex age age_sq rural edu_f edu_m ///
occ f v`n' c.v`n'#c.school if syear==`n'
```

REPLICATION AND COMPARIS
RESULTS
CONCLUSION

RESULTS

M: Results Comparison I

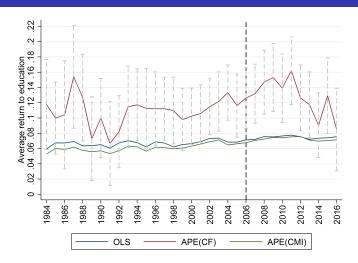

FIGURE 5: Replication results: Comparison between OLS, CMI and CF

Luisa Hammer and Marcelo Avila

M: RESULTS COMPARISON II

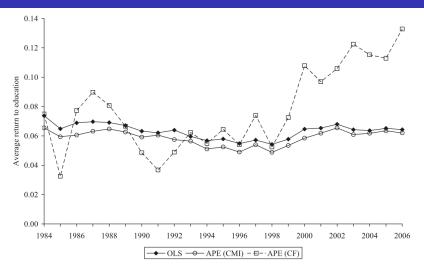

FIGURE 6: Original Results (GP 2010, pg.30)

Luisa Hammer and Marcelo Avila

M: Estimated returns on education

- Estimates from OLS and CMI are similar, yet, CMI produces lower estimates which points to a positive self-selection bias
- Generally, CF estimates are much more volatile and less precise

Differences between replicated and original estimations

- Our OLS estimates are on average larger than those of Gebel and Pfeiffer (2010) by 0.004 percentage points
- Our CMI estimates are on average larger than those of Gebel and Pfeiffer (2010) by 0.002 percentage points (first years lower, than larger)
- Our CF estimates are on average significantly larger by 0.032 percentage points, though the divergence gets smaller from 2000 onwards

L: Control function estimates I

Instrumental variable in first step

- Number of siblings is significant at the 0.1% level for all years
- As expected, the number of siblings has a negative impact on the years of schooling (the estimates range between -0.13 and -0.23)
- We would assume that the instrument does not directly affect the error term in the wage equation

Coefficients of the control functions

- $\ \ \, \gamma_1$ is negative for majority of years, yet very small and insignificant in all years
 - Gebel and Pfeiffer (2010) estimate a positive coefficient in the 1980s and 1990s - but also insignificant
- lacksquare γ_2 is negative and close to zero for most years
 - Indicates that those with unexpectedly high education have lower returns to education

L: Control function estimates II

- Similarly, they are only slightly significant in the 1980s, and stronger significant in the early 2000s
- The estimates are very similar to those of Gebel and Pfeiffer (2010)
- that both coefficients are (mostly) negative hints that educational expansion caused more "less abled" to achieve higher education

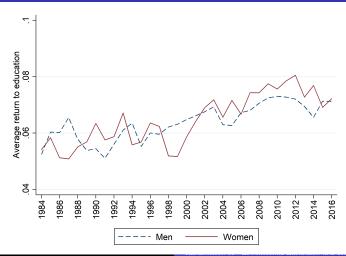

L: RESULTS: CONTROL FUNCTION (REPLICATION)
